**Abstract.** In the context of platforms that host user-generated content (UGC), decentralized content curation is the process through which uploaded posts are ranked and filtered based exclusively on users' feedback. Platforms such as the blockchain-based Steemit<sup>1</sup> employ this type of curation while providing monetary incentives to promote the visibility of quality posts. Popular centralized aggregation platforms such as Reddit and YouTube rely crucially on users' feedback to rank content; the sheer volume of content excludes expert-based ranking and the danger of manipulation rules out purely algorithmic techniques. However, in contrast to Steemit and other decentralized cases, centralized platforms need not be completely transparent on the details of their approach.

In the present work, we formally define an abstract post-voting mechanism that realizes the process of decentralized content curation and provide a measure of its success in sorting posts according to their quality. We then define a particular mechanism that models Steemit and provide the conditions under which it correctly orders posts. We finally provide the results of simulating the evolution of the system in relevant scenarios.

## 1 Introduction

The modern Internet contains an immense amount of data; a single user can only consume a tiny fraction in a reasonable amount of time. Therefore, any widely used platform that hosts user-generated content must employ a content curation mechanism. Content curation can be understood as the set of mechanisms which rank, aggregate and filter relevant information. In recent years, popular news aggregation sites like Reddit<sup>2</sup> or Hacker News<sup>3</sup> have established crowdsourced curation as the primary way to filter content for their users. Crowdsourced content curation, as

---

<sup>1</sup> <https://steemit.com/> Accessed: 2018-09-10

<sup>2</sup> <https://www.reddit.com/> Accessed: 2018-09-10.

<sup>3</sup> <https://news.ycombinator.com/> Accessed: 2018-09-10.

opposed to more traditional techniques such as expert- or algorithmic-based curation, orders and filters content based on the ratings and feedback of the users themselves, obviating the need for a central moderator by leveraging the wisdom of the crowd [1].

The decentralized nature of crowdsourced curation makes it a suitable solution for ranking user-generated content in blockchain-based content hosting systems. The aggregation and filtering of user-generated content emerges as a particularly challenging problem in permissionless blockchains, as any solution that requires a concrete moderator implies that there exists a privileged party, which is incompatible with a permissionless blockchain. Moreover, public blockchains are easy targets for Sybil attacks, as any user can create new accounts at any time for a marginal cost. Therefore, on-chain mechanisms to resist the effect of Sybil users are necessary for a healthy and well-functioning platform; traditional counter-Sybil mechanisms [2] are much harder to apply in the case of blockchains due to the decentralized nature of the latter. The functions performed by moderators in traditional content platforms need to be replaced by incentive mechanisms that ensure self-regulation. Having the impact of a vote depend on the number of coins the voter holds is an intuitively appealing strategy to achieve a proper alignment of incentives for users in decentralized content platforms; specifically, it can render Sybil attacks impossible. However, the correct design of such systems is still an unsolved problem. Blockchains have created a new economic paradigm where users are at the same time equity holders in the system, and leveraging this property in a robust manner constitutes an interesting challenge. A variety of projects have designed decentralized content curation systems [3,4,5]. However, a deep understanding of the properties of such systems is still lacking.

In the current work, we develop a theoretical model of a post-voting system which sorts the posts created by users in a distributed and crowdsourced manner. Our model is constituted by  $N$  players who contribute votes in a round-based curation process. The impact of each vote depends on the number of coins held by the player. The posts are arranged in a list, sorted by the value of votes received, resembling the front-page model of Reddit or Hacker News. In the model, players vote according to their subjective opinion on the quality of the posts and have a limited attention span  $\text{attSpan}$ . Following previous academic work, we represent each player's opinion on each post (i.e. likability) with a numerical value  $n \in [0, 1]$  [6,1]. The objective quality of a post will be calculated as the simple summation of all players' likabilities for the post in question. To measure the properties of such a post-voting system, we say that the sys-

tem *t-converges* if the  $t$  first articles are ordered according to the objective quality of the posts at the end of the execution. After defining and formalizing a general post-voting system, we particularize it to model Steemit, a social media platform based on the Steem blockchain. We particularize our analysis on Steemit as we recognize that the explicit financial incentives present in its blockchain-based platform are better suited to our analysis than traditional sites such as Reddit or Hacker News, studied in the previous literature. We develop a simulation to help us parametrize Steemit according to our post-voting model and then we prove the conditions under which Steemit *t-converges* (i.e. it is successful in the content curation process). Our analysis of Steemit’s post-voting system aims to provide a better framework for the better design of future decentralized curation platforms.

### **Our Contributions.**

- Original treatment following cryptography and simulation-based techniques to model crowdsourced content curation, in opposition to previous academic work which have leaned more towards an analytical and game-theoretic approach.
- Taking in account of subjective likeabilities, the effect of rounds and an agnostic likeability distribution treatment.
- Measurement of the influence of coin-holding (wealth-distribution) in the effectivity of post sorting. New paradigm present in blockchain based systems (main difference with Reddit-like platforms.)
- Proof that Steem does not *t-converge* with the parameters currently used in their implementation. Insights to improve the curation quality of the trending section of steem.
- (Maybe)Impact of the curation quality when greedy players are present in the system.

## **2 Related Work**

Motivated by the widespread adoption of crowdsourced aggregation sites such as Reddit, several research efforts [1,?,9] have aimed to model the mechanics and incentives for users in User-generated content (UGC) platforms. Most of the academic work in the field have analyzed content curation from an incentives and game-theoretic stand-point [6,7,8,9]. We recognize the value of these past efforts and we adopt some of the components used in these models such as the quality distribution of the articles

and the user’s attention span. However, our approach is different as we describe the mechanics of post-voting systems from a computational, rather than an analytical angle. Furthermore, we draw inspiration from the real-world paradigm of Cryptography [10] in the definition of convergence.

We are aware of the limitations imposed by Arrow’s impossibility theorem [11]. Nevertheless, since we avoid a general game-theoretic approach, these limitations do not impact the outcomes of our work. In particular, we restrict the behavior of agents to a specific set of choices and we do not permit strategic decisions. We also acknowledge previous work in voting procedures in the field of social choice...(maybe add later).

The governance of online communities such as Wikipedia has been thoroughly studied in previous academic work [12,13]. However, the financially incentivized governance processes in blockchain systems, where the voters are at the same time equity-holders have still many open research questions [14,15]. Beyond the Steem blockchain, coin-holder voting systems are present in decentralized platforms such as DAOs [16] and in different blockchain protocols [17]. However, most of these systems use coin-holder voting processes to agree on a value or take a consensual decision. In the present work we do not tackle the issue of decentralized governance in the strictest sense. Nevertheless, given that the voting procedure as described here largely defines the state of the system, our results are intimately related to the topic of decentralized governance.

### 3 Model

#### 1 Notation

- We denote the set of all probability distributions on set  $A$  as  $\mathcal{D}(A)$ .
- We denote the powerset of a set  $A$  with  $2^A$ .
- $a||b$  denotes the concatenation of  $a$  and  $b$ .
- Let  $n \in \mathbb{N}^*$ .  $[n]$  denotes  $\{1, 2, \dots, n\}$ .

#### 2 Properties of Post Voting Systems

A post voting system has the objective to arrange the posts according to the preferences of the participants. The ideal order is defined based on the likeability matrix for the posts.

**Definition 1 (Post).** *Let  $N \in \mathbb{N}^*$ . A post is defined as  $p = (i, l)$ , with  $i \in [N], l \in [0, 1]^N$ .*

- **Author.** The first element of a post is the index of its creator,  $i$ .
- **Likeability.** The likeability of a post is defined as  $l \in [0, 1]^N$ .

Let  $M \in \mathbb{N}^*$  the number of posts. Then  $\forall j \in [M]$ , let  $\text{creator}_j \in [N]$ ,  $l_j \in [0, 1]^N$  and  $p_j = (\text{creator}_j, l_j)$ . The set of all posts is  $\mathcal{P} = \bigcup_{j=1}^M \{p_j\}$ .

**Definition 2 (Ideal Score of a post).** Let post  $p = (m, l)$ . We define the ideal score of  $p$  as  $\text{idealSc}(p) = \sum_{i=1}^N l_i$ .

The ideal score of a post is a single number that represents its overall worth to the community. By using simple summation, we assume that the opinions of all players have the same weight. In an ordered list of posts where higher posts are more visible, the “common interest” would require that a post with higher ideal score appear before another post with a lower score.

**Definition 3 ( $t$ -Ideal Post Order).** Let  $\mathcal{P}$  a list of posts. We say that  $\mathcal{P}$  is in  $t$ -ideal order and that the property  $\text{IDEAL}^t(\mathcal{P})$  holds if

$$\forall i < j \in |t|, \text{idealSc}(\mathcal{P}[i]) \geq \text{idealSc}(\mathcal{P}[j]) \quad .$$

**Definition 4 (Post-Voting System).** A tuple  $\mathcal{S} = (\text{INIT}, \text{AUX}, \text{HANDLEVOTE}, \text{VOTE})$  of four algorithms. The four algorithms parametrize the following two ITMs:

$\mathcal{G}_{\text{Feed}}$  is a global functionality that accepts two messages: **read**, which responds with the current list of posts and **vote**, which can take various arguments and does whatever is defined in  $\text{HANDLEVOTE}$ .

$\Pi_{\text{honest}}$  is a protocol that sends **read** and **vote** messages to  $\mathcal{G}_{\text{Feed}}$  whenever it receives (**activate**) from  $\mathcal{E}$ .

---

**Algorithm 1**  $\mathcal{G}_{\text{Feed}}(\text{INIT}, \text{AUX}, \text{HANDLEVOTE})(\mathcal{P}, \text{initArgs})$

---

- 1: Initialization:
  - 2:    $\mathcal{U} \leftarrow \emptyset$  ▷ Set of players
  - 3:    $\text{INIT}(\text{initArgs})$
  - 4:
  - 5: Upon receiving (**read**) from  $u_{\text{pid}}$ :
  - 6:    $\mathcal{U} \leftarrow \mathcal{U} \cup \{u_{\text{pid}}\}$
  - 7:    $\text{aux} \leftarrow \text{AUX}(u_{\text{pid}})$
  - 8:   Send (**posts**,  $\mathcal{P}$ ,  $\text{aux}$ ) to  $u_{\text{pid}}$
  - 9:
  - 10: Upon receiving (**vote**,  $\text{ballot}$ ) from  $u_{\text{pid}}$ :
  - 11:    $\text{HANDLEVOTE}(\text{ballot})$
-

---

**Algorithm 2**  $\Pi_{\text{honest}}(\text{VOTE})$ 

---

- 1: Upon receiving (**activate**) from  $\mathcal{E}$ :
  - 2:   Send (**read**) to  $\mathcal{G}_{\text{Feed}}$
  - 3:   Wait for response (**posts**,  $\mathcal{P}$ , aux)
  - 4:   ballot  $\leftarrow \text{VOTE}(\mathcal{P}, \text{aux})$
  - 5:   Send (**vote**, ballot) to  $\mathcal{G}_{\text{Feed}}$
- 

**Definition 5 (Post-Voting System Activation Message).** We define  $\text{act}_{\text{pid}}$  as the message (**activate**, pid), sent to  $u_{\text{pid}}$ .

**Definition 6 (Execution Pattern).** Let  $N, R \in \mathbb{N}^*$ .

$$\text{ExecPat}_{N,R} = \left\{ (\text{act}_{\text{pid}_1}, \dots, \text{act}_{\text{pid}_{NR}}) : \forall i \in [R], \forall k \in [N], \exists j \in [N] : \text{pid}_{(i-1)N+j} = k \right\} ,$$

*i.e. activation messages are grouped in  $R$  rounds and within each round each player is **activated** exactly once. The order of activations is not fixed.*

*Let Environment  $\mathcal{E}$  that sends messages  $\text{msgs} = (\text{act}_{\text{pid}_1}, \dots, \text{act}_{\text{pid}_n})$  sequentially. We say that  $\mathcal{E}$  respects  $\text{ExecPat}_{N,R}$  if  $\text{msgs} \in \text{ExecPat}_{N,R}$ . (Note: this implies that  $n = NR$ .)*

**Definition 7 ( $(N, R, M, t)$ -convergence under honesty).** We say that a post-voting system  $\mathcal{S} = (\text{INIT}, \text{AUX}, \text{HANDLEVOTE}, \text{VOTE})$   $(N, R, M, t)$ -converges under honesty (or  $t$ -converges under honesty for  $N$  players,  $R$  rounds and  $M$  posts) if, for every input  $\mathcal{P}$  such that  $|\mathcal{P}| = M$ , for every  $\mathcal{E}$  that respects  $\text{ExecPat}_{N,R}$  and given that all protocols execute  $\Pi_{\text{honest}}$ , it holds that after  $\mathcal{E}$  completes its execution pattern,  $\mathcal{G}_{\text{Feed}}$  contains a post list  $\mathcal{P}$  such that  $\text{IDEAL}^t(\mathcal{P})$  is true.

TODO: Discuss: Is  $R$  missing from Steem system? Maybe add "Let  $N, R \in \mathbb{N}^*$ , ..., controlled by an Environment that respects  $\text{ExecPat}_{N,R}$  and the following ...".

**Definition 8 (Steem system).** The Steem system is the post voting system  $\mathcal{S}$  with parameters  $\mathbf{SP} \in \mathbb{N}^{*N}$ ,  $a, b, \text{regen} \in [0, 1] : a+b < 1$ ,  $\text{attSpan} \in \mathbb{N}^*$  and the following parametrizing procedures:

---

**Algorithm 3** INIT ( $\mathbf{SP}, \text{attSpan}, a, b, \text{regen}$ )

---

```
1: Store input parameters as constants
2:  $r \leftarrow 1$ 
3:  $\text{lastVoted} \leftarrow \underbrace{(0, \dots, 0)}_N$ 
4:  $\mathbf{VP} \leftarrow \underbrace{(1, \dots, 1)}_N$ 
5:  $\text{scores} \leftarrow \underbrace{(0, \dots, 0)}_{|\mathcal{P}|}$ 
```

---

---

**Algorithm 4** AUX

---

```
1: return ( $\mathbf{SP}, \text{attSpan}, a, b, r, \text{regen}$ )
```

---

---

**Algorithm 5** HANDLEVOTE ( $\text{ballot}, u_{\text{pid}}$ )

---

```
1: if  $\text{lastVoted}_{\text{pid}} \neq r$  then ▷ One vote per player per round
2:    $\mathbf{VP}_{\text{pid}, r} \leftarrow \mathbf{VP}_{\text{pid}}$  ▷ For proofs
3:    $\mathbf{VP}_{\text{pid}} \leftarrow \max \{ \mathbf{VP}_{\text{pid}} + \text{regen} \cdot (r - \text{lastVoted}_{\text{pid}}), 1 \}$  ▷ TODO: Remove
    $(r - \text{lastVoted}_{\text{pid}})?$ 
4:    $\mathbf{VP}_{\text{reg}_{\text{pid}, r}} \leftarrow \mathbf{VP}_{\text{pid}}$  ▷ For proofs
5:   if  $\text{ballot} \neq \text{null}$  then
6:     Parse ballot as  $(p, \text{weight})$ 
7:      $\text{cost} \leftarrow a \cdot \mathbf{VP}_{\text{pid}} \cdot \text{weight} + b$ 
8:     if  $\mathbf{VP}_{\text{pid}} - \text{cost} \geq 0$  then
9:        $\text{score} \leftarrow \text{cost} \cdot \mathbf{SP}_{\text{pid}}$ 
10:       $\mathbf{VP}_{\text{pid}} \leftarrow \mathbf{VP}_{\text{pid}} - \text{cost}$ 
11:    else
12:       $\text{score} \leftarrow \mathbf{VP}_{\text{pid}} \cdot \mathbf{SP}_{\text{pid}}$ 
13:       $\mathbf{VP}_{\text{pid}} \leftarrow 0$ 
14:    end if
15:     $\text{scores}_p \leftarrow \text{scores}_p + \text{score}$ 
16:  end if
17:   $\text{lastVoted}_{\text{pid}} \leftarrow r$ 
18: end if
19: if  $\forall i \in [N], \text{lastVoted}_i = r$  then ▷ round over
20:    $\mathcal{P} \leftarrow \text{ORDER}(\mathcal{P}, \text{scores})$  ▷ order posts by votes
21:    $\mathcal{P}_r \leftarrow \mathcal{P}$  ▷ For proofs
22:    $r \leftarrow r + 1$ 
23: end if ▷ TODO: count rounds? simplify with set of voted and check of length?
```

---

---

**Algorithm 6** VOTE( $\mathcal{P}$ , aux)

---

```
1: Store aux contents as constants
2: voteRounds  $\leftarrow$  VOTEROUNDS( $R, |\mathcal{P}|$ )

39:   return voteRounds
40: end function
```

---

**Theorem 1.** *The Steem system  $(N, R, M, M)$ -converges if and only if  $SP$  is constant and  $R - 1 \geq (M - 1) \left\lceil \frac{a+b}{\text{regen}} \right\rceil$ .*

*Proof.* – ( $\Leftarrow$ ) Suppose that

$$R - 1 \geq (M - 1) \left\lceil \frac{a + b}{\text{regen}} \right\rceil \quad (1)$$

and  $\forall i \in [N], \mathbf{SP}_i = c$ .

Let  $\text{pid} \in [N]$ . In this case it is  $R \geq M$  and according to **VOTETHIS-ROUND** in Algorithm 6,  $u_{\text{pid}}$  votes non-null in rounds  $(r_1, \dots, r_M)$  with  $r_i = \left\lfloor (i - 1) \frac{R-1}{M-1} \right\rfloor + 1$ . Observe that:

$$(1) \Rightarrow \frac{R-1}{M-1} \geq \left\lceil \frac{a+b}{\text{regen}} \right\rceil \xrightarrow[\text{integer}]{\text{rhs}} \left\lfloor \frac{R-1}{M-1} \right\rfloor \geq \left\lceil \frac{a+b}{\text{regen}} \right\rceil, \quad (2)$$

$$\forall i \in [M] \setminus \{1\}, r_i \in \left\{ r_{i-1} + \left\lfloor \frac{R-1}{M-1} \right\rfloor, r_{i-1} + \left\lceil \frac{R-1}{M-1} \right\rceil \right\}. \quad (3)$$

From (2) and (3) we have that  $\forall i \in [M-1], r_{i+1} - r_i \geq \left\lceil \frac{a+b}{\text{regen}} \right\rceil$ . We will now prove by induction that  $\forall i \in [M], \mathbf{VP}_{\text{pid}, r_i} = 1$ .

- For  $i = 1$ ,  $\mathbf{VP}_{\text{pid}, 1} = 1$  by (Algorithm 3, line 4).
- Let  $\mathbf{VP}_{\text{pid}, r_i} = 1$ . Until  $r_{i+1}$ , a single non-null vote is cast by  $u_{\text{pid}}$ , which reduces  $\mathbf{VP}_{\text{pid}}$  by at most  $a + b$  (Algorithm 5, line 7) and at least  $\left\lceil \frac{a+b}{\text{regen}} \right\rceil$  regenerations, each of which replenishes  $\mathbf{VP}_{\text{pid}}$  by  $\text{regen}$ . Thus

$$\mathbf{VP}_{\text{pid}, r_{i+1}} \geq \min \left\{ \mathbf{VP}_{\text{pid}, r_i} - a - b + \text{regen} \left\lceil \frac{a+b}{\text{regen}} \right\rceil, 1 \right\} \geq 1.$$

But  $\mathbf{VP}_{\text{pid}}$  cannot exceed 1 (line 4), thus  $\mathbf{VP}_{\text{pid}, r_{i+1}} = 1$ .

Since the above holds for every  $\text{pid} \in [N]$ , we have that at the end of the execution, all votes have been cast with full voting power, thus  $\forall p = (i, l) \in \mathcal{P}_R, \text{scores}_p = c \left( Nb + a \sum_{\text{pid}=1}^N l_{\text{pid}} \right)$  and the posts in  $\mathcal{P}_R$  are sorted by decreasing score (Algorithm 5, line 20). We observe that

$$\begin{aligned} \forall p_1 = (j^1, l^1) \neq p_2 = (j^2, l^2) \in \mathcal{P}_R, \text{idealSc}(p_1) > \text{idealSc}(p_2) \Rightarrow \\ \sum_{i=1}^N l_i^1 > \sum_{i=1}^N l_i^2 \Rightarrow c \left( Nb + a \sum_{i=1}^N l_i^1 \right) > c \left( Nb + a \sum_{i=1}^N l_i^2 \right). \end{aligned}$$

Thus all posts will be ordered according to their ideal scores; put otherwise,  $\text{IDEALSCORE}^M(\mathcal{P}_R)$  holds.

- (**SP** variable  $\Rightarrow$  no convergence) Let  $\mathcal{P} = [(1, (a_1, \dots, a_N)), (1, (b_1, \dots, b_N)), (1, (0, \dots, 0)), \dots, (1, (0, \dots, 0))]$  such that the following linear constraints are simultaneously feasible:

$$\begin{aligned} \sum_{i=1}^N a_i &> \sum_{i=1}^N b_i \\ \sum_{i=1}^N \text{SP}_i a_i &< \sum_{i=1}^N \text{SP}_i b_i \end{aligned}$$

I think that's always possible if SP is not constant.

- (inequality doesn't hold  $\Rightarrow$  no convergence) Suppose that

$$\begin{aligned} R - 1 &< (M - 1) \left\lceil \frac{a + b}{\text{regen}} \right\rceil \\ \text{and } \forall i \in [N], \text{SP}_i &= c. \end{aligned} \tag{4}$$

If  $R < M$ , we consider two cases:

•

$$\text{attSpan} + R \leq M \tag{5}$$

In this case, no player can ever vote for the last post, as we will show now. Let  $\text{pid} \in N, i \in [R]$  and  $v_i$  the index of the last post that has ever been in  $u_{\text{pid}}$ 's attention span until the end of round  $i$ . It is  $v_1 = \text{attSpan}$  and  $\forall i \in [R] \setminus \{1\}, v_i = v_{i-1} + 1$ , since in every round  $u_{\text{pid}}$  votes for a single post and the first unvoted post of the list is added to their attention span. Note that, since this mechanism is the same for all players, the same unvoted post is added to all players' attention span at every round. Thus  $v_R = \text{attSpan} + R - 1 \stackrel{(5)}{<} M$ . We deduce that  $u_{\text{pid}}$  never has the chance to vote for the last post.

The above observation naturally leads us to the following counterexample: Let

$$\begin{aligned} \text{strongPost} &= \left( 1, \underbrace{(1, \dots, 1)}_N \right) \\ \text{nullPost} &= \left( 1, \underbrace{(0, \dots, 0)}_N \right) \\ \mathcal{P} &= \left[ \underbrace{\text{nullPost}, \dots, \text{nullPost}}_{M-1}, \text{strongPost} \right] \end{aligned}$$

$\forall i \in [M-1]$ , it is  $\text{idealSc}(\mathcal{P}[M]) > \text{idealSc}(\mathcal{P}[M])$ , thus  $\forall \mathcal{P}'$  that contain the same posts as  $\mathcal{P}$  and  $\text{IDEAL}^1(\mathcal{P}')$  holds, it is  $\mathcal{P}'[1] = \mathcal{P}[M]$ . However, since the last post is not voted by any player and the first post is voted by at least one player, it is  $\text{sc}_R(\mathcal{P}[1]) > \text{sc}_R(\mathcal{P}[M])$ , thus  $\text{IDEAL}^1(\mathcal{P}_R)$  does not hold.

- $\text{attSpan} + R > M$

TODO

Assume  $R \geq M$ . In this case, all posts receive a vote by all players. Consider  $\mathcal{P}^1 = 1^{M \times N}$  and  $\text{pid} \in [N]$ . Let

$$i \in [M] : \left( \mathbf{VPreg}_{\text{pid}, r_i} < 1 \wedge \nexists i' < i : \mathbf{VPreg}_{\text{pid}, r_{i'}} < 1 \right) ,$$

i.e.  $i$  is the first round in which  $u_{\text{pid}}$  votes with less than full voting power. Since the first round is a voting round and the voting power of all players is full, it is  $i \geq 2$ . Such a round exists for the following reason:

If  $\nexists i \in [M] : \left( \mathbf{VPreg}_{\text{pid}, r_i} < 1 \wedge \nexists i' < i : \mathbf{VPreg}_{\text{pid}, r_{i'}} < 1 \right)$ , then  $\forall i \in [M], \mathbf{VPreg}_{\text{pid}, r_i} = 1 \Rightarrow \forall i \in [M] \setminus \{1\}, r_i \geq r_{i-1} + \left\lceil \frac{a+b}{\text{regen}} \right\rceil$  to have enough rounds to replenish the voting power after a full-weight, full-voting power vote. Thus  $r_M \geq 1 + (M-1) \left\lceil \frac{a+b}{\text{regen}} \right\rceil > R$ , contradiction. Since all players follow the same voting pattern, the voting power of all players in each round is the same. Let  $\text{rVP} = \mathbf{VPreg}_{1, r_i}$ . For now assume  $2|N$  and  $\text{attSpan} < i \vee i > 2$ . TODO: prove rest. Let  $0 < \gamma < 1$  and  $0 < \epsilon < \gamma \frac{N-3}{N-1} (1 - \text{rVP})$ .

$$\begin{aligned} \text{weakPost} &= \left( 1, \left( \underbrace{1, \dots, 1}_{N/2}, \underbrace{\gamma - \epsilon, \dots, \gamma - \epsilon}_{N/2} \right) \right) , \\ \text{strongPost} &= \left( 1, \left( \underbrace{\gamma, \dots, \gamma}_{N/2}, \underbrace{1, \dots, 1}_{N/2} \right) \right) , \\ \text{nullPost} &= \left( 1, \left( \underbrace{0, \dots, 0}_N \right) \right) , \\ \mathcal{P} &= \left[ \underbrace{\text{weakPost}, \dots, \text{weakPost}}_{i-1}, \text{strongPost}, \underbrace{\text{nullPost}, \dots, \text{nullPost}}_{M-i} \right] . \end{aligned}$$

First of all, it is  $\forall j \in [i-1], \text{idealSc}(\mathcal{P}[j]) = \frac{N}{2} (1 + \gamma - \epsilon) < \frac{N}{2} (1 + \gamma) = \text{idealSc}(\mathcal{P}[i])$  and  $\forall j \in \{i+1, \dots, M\}, \text{idealSc}(\mathcal{P}[j]) = 0 < \text{idealSc}(\mathcal{P}[i])$ ,

thus the strong post has strictly the highest ideal score of all posts and as a result,  $\forall \mathcal{P}'$  that contains the same posts as  $\mathcal{P}$  and  $\text{IDEAL}^1(\mathcal{P}')$  holds, it is  $\mathcal{P}'[1] = \mathcal{P}[i]$ .

We observe that all players like both weak and strong posts more than null posts, thus no player will vote for a null post unless her attention span contains only null posts. This can happen in two cases: First, if the player has not yet voted for all non-null posts, but the first attSpan posts of the list, excluding already voted posts, are null posts. Second, if the player has already voted for all non-null posts. For a null post to rank higher than a non-null one, it must be true that there exists one player that has cast the first vote for the null post. However, since the null posts are initially at the bottom of the list and it is impossible for a post to improve its ranking before it is voted, we deduce that this first vote can be cast only after the voter has voted for all non-null posts. We deduce that all players vote for all non-null posts before voting for any null post.

We will now see that the first  $\frac{N}{2}$  players vote first for all weak posts and then for the strong post. These players like the weak posts more than the strong post. As we saw, they will not vote any null post before voting for all non-null ones. If  $\text{attSpan} > 1$  they vote for the strong post only when all other posts in their attention span are null ones and thus they will have voted for all weak posts already. If  $\text{attSpan} = 1$  and since no post can increase its position before being voted, the strong post will become “visible” for all players only once they have voted for all weak posts. Thus in both cases the first  $\frac{N}{2}$  players vote for the strong post only after they have voted for all weak posts first. The two previous results combined prove that the first  $\frac{N}{2}$  players vote for the strong post in round  $r_i$  exactly. We also observe that these players have experienced the exact same voting power reduction and regeneration as in the case of  $\mathcal{P}^1$  since they voted only for posts with likeability 1, thus in round  $r_i$  their voting power after regeneration is exactly the same as in the case of  $\mathcal{P}^1$  :  $\forall \text{pid} \in \left[\frac{N}{2}\right], \mathbf{VP}_{\text{pid}, r_i} = \text{rVP}$ .

We observe that the first  $\frac{N}{2}$  players vote for all weak posts with full voting power. As for the last  $\frac{N}{2}$  players, we observe that, if  $\text{attSpan} < i$ , they all vote for the first weak post of the list in the first round, and thus with full voting power. If  $\text{attSpan} \geq i$  and  $i > 2$ , they vote for the strong post in the first round and for the first weak post in  $r_2$  with full voting power. Thus in all cases the last  $\frac{N}{2}$  players vote for the first weak post with full voting power. Therefore, the score

of the first weak post at the end of the execution is  $\text{sc}_R(\mathcal{P}[1]) = c\left(\frac{N}{2}(a+b) + \frac{N}{2}((\gamma - \epsilon)a + b)\right)$ .

On the other hand, at the end of the execution the strong post has been voted by the first  $\frac{N}{2}$  players with rVP voting power and by the last  $\frac{N}{2}$  players with at most full voting power, thus its final score will be at most  $\text{sc}_R(\mathcal{P}[i]) \leq c\left(\frac{N}{2}(\text{rVP} \cdot \gamma a + b) + \frac{N}{2}(a+b)\right)$ . It is

$$\begin{aligned} \epsilon < \gamma(1 - \text{rVP}) &\Rightarrow \\ c\left(\frac{N}{2}(a+b) + \frac{N}{2}((\gamma - \epsilon)a + b)\right) &< c\left(\frac{N}{2}(\text{rVP} \cdot \gamma a + \frac{N}{2}(a+b))\right) \Rightarrow \\ \text{sc}_R(\mathcal{P}[i]) &< \text{sc}_R(\mathcal{P}[1]) . \end{aligned}$$

Thus  $\mathcal{P}_R[1] \neq \mathcal{P}[i]$  and  $\text{Ideal}^1(\mathcal{P}_R)$  does not hold.

As for the case when  $N$  is odd, we can simply assume that the likeability of the first  $i$  posts (weak and strong) for the last player is  $\gamma$ , whereas the likeability of the last  $M - i$  posts (the null posts) is 0. This means that the first player votes first for the weak and strong posts and then for the null posts. We observe that the ideal score of the strong post is still strictly higher than the rest. We have the following changes:

$$\begin{aligned} \text{sc}_R(\mathcal{P}[i]) &\leq c\left(\frac{N-1}{2}(\text{rVP} \cdot \gamma a + b) + \frac{N-1}{2}(a+b) + \gamma a + b\right) , \\ \text{sc}_R(\mathcal{P}[1]) &\geq c\left(\frac{N-1}{2}(a+b) + \frac{N-1}{2}((\gamma - \epsilon)a + b) + \text{rVP} \cdot \gamma a + b\right) . \end{aligned}$$

For the strong post to have strictly lower score than the first weak one, it must hold that

$$\epsilon < \gamma \frac{N-3}{N-1} (1 - \text{rVP}) .$$

□

The above result is tight. If the conditions are violated the above theorem is not true.

## 4 Results

Steem won't achieve high quality posts.

## 5 Further Work

Posts at any time

## 6 Conclusion

Keep inventing new decentralized content curation platforms.

## 7 Acknowledgements

We thank @seriousposter for their invaluable posts analyzing Steem and our mums for the cookies.
